## Momentum \& Impulse

How does a karate expert chop through cement blocks with a bare hand?
Why does a fall onto a wooden floor hurt less than onto a cement floor?
Why do people in larger vehicles usually end up with fewer injuries in accidents?
It's easy to come up with answers like...
"The karate guy is strong!"
"Wood is softer!"
"Bigger is better!"
but have you ever stopped to consider the why? That's when physics comes walking in, waving explanations in everyone's face.

Spend a couple minutes right now to come up with explanations of the three situations using physics principles you have learned so far. Keep these situations and your explanations in mind as you cover this section on momentum and impulse. See if you need to modify or change your explanations based on what you learn.

Momentum Impulse Newton Graphing

## Momentum

Momentum is an idea that combines mass and velocity into one package. It is an idea that is similar to inertia and kinetic energy.

Inertia is the property of an object to stay at rest or in motion.
Kinetic energy is the amount of energy that an object due to its motion. $\left(\mathrm{E}_{\mathrm{k}}=1 / 2 \mathrm{mv}^{2}\right)$
Momentum is not truly either of these, but ends up like a mix of the two.

- If you compare and contrast momentum and kinetic energy, you'll notice a couple things...
- First, they both have mass and velocity in their formulas.
- Second, kinetic energy has to do with ability to do work, momentum doesn't.
- Although they are similar, they are not the same.
- We haven't given you any way to calculate inertia yet, so is momentum the same as inertia?
- Not really. Inertia is a concept, not something that is directly measured.

Momentum is calculated by multiplying the mass and velocity of an object.

$$
\mathrm{p}=\mathrm{mv}
$$

$$
\mathrm{p}=\text { momentum }(\mathrm{kg} \mathrm{~m} / \mathrm{s})
$$

$$
\mathrm{m}=\operatorname{mass}(\mathrm{kg})
$$

$$
\mathrm{v}=\text { velocity }(\mathrm{m} / \mathrm{s})
$$

Notice that momentum does not have a nice derived unit, although I would appreciate it if you lobbied physicists to name it the "Clintberg" in my honor. For now you'll just need to give the units " $\mathrm{kg} \mathrm{m} / \mathrm{s}$ "

Example 1: A 1000 kg car is moving at $10 \mathrm{~km} / \mathrm{h}$. Determine the momentum of the car.

$$
\begin{aligned}
& \mathrm{p}=\mathrm{mv} \\
& \mathrm{p}=1000 \mathrm{~kg}(2.78 \mathrm{~m} / \mathrm{s}) \\
& \mathrm{p}=2.78 \mathrm{e} 3 \mathrm{~kg} \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

## Momentum Impulse Newton Graphing

## Impulse

The simple definition for impulse is that it is a change in momentum.

- If an object's velocity changes, there is a change in momentum, so there must be an impulse
- We assume that you are not going to change the mass of an object.

## $\Delta \mathrm{p}=\mathrm{m} \Delta \mathrm{v}$

$$
\begin{array}{r}
\Delta p=\text { impulse }(\text { change in momentum })(\mathrm{kgm} / \mathrm{s}) \\
m=\operatorname{mass}(\mathrm{kg}) \\
\Delta v=\text { change in velocity }\left(\mathrm{v}_{\mathrm{f}}-\mathrm{v}_{\mathrm{i}}\right)(\mathrm{m} / \mathrm{s})
\end{array}
$$

Example 2: A box of tic tacs $(15 \mathrm{~g})$ is sliding along the table at $5.0 \mathrm{~m} / \mathrm{s}$. I try to stop it, but only slow it down to $1.6 \mathrm{~m} / \mathrm{s}$. Determine the impulse I impart to the box.

$$
\begin{aligned}
& \Delta \mathrm{p}=\mathrm{m} \Delta \mathrm{v} \\
& \Delta \mathrm{p}=\mathrm{m}\left(\mathrm{v}_{\mathrm{f}}-\mathrm{v}_{\mathrm{i}}\right) \\
& =0.015 \mathrm{~kg}(1.6 \mathrm{~m} / \mathrm{s}-5.0 \mathrm{~m} / \mathrm{s}) \\
& \Delta \mathrm{p}=-0.051 \mathrm{~kg} \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

The negative sign just identifies that my impulse was in the negative direction. Momentum was taken away from the object.

But wait a second, if an impulse changes the velocity of the object, that means it's accelerating.

- Acceleration of an object can only occur if a force is acting on the object... so force must be related to impulse in some way.
- This leads us to the link to Newton.

Momentum Impulse Newton Graphing

## Newton

When Newton came up with his $2^{\text {nd }}$ Law of motion, he didn't write it in the form we usually see it today, $\mathrm{F}=\mathrm{ma}$.

- Remember that he was playing around with some new ideas, and didn't necessarily look for the "easiest" way to state his theories.
- Instead, he kept talking about the "quantity of motion" of an object, what we today call momentum.
- When he stated his $2^{\text {nd }}$ law he said the force is proportional to the rate of change in the momentum.

$$
F=\frac{\Delta p}{\Delta t}
$$

Notice that you can solve this formula to get what we now consider the "standard" form of the $2^{\text {nd }}$ law...

$$
\begin{gathered}
F=\frac{\Delta p}{\Delta t} \text { but we know that } \Delta \mathrm{p}=\mathrm{m} \Delta \mathrm{v} \\
F=\frac{m \Delta v}{\Delta t} \text { and we also know that } a=\frac{\Delta v}{\Delta t} \\
\mathrm{~F}=\mathrm{ma}
\end{gathered}
$$

We can also come up with a different (and more versatile) version of the impulse formula.

- The formula you were first given was...

$$
\Delta \mathrm{p}=\mathrm{m} \Delta \mathrm{v}
$$

- But we just saw that Newton used impulse in his formulas...

$$
F=\frac{\Delta p}{\Delta t}
$$

which becomes
$\Delta \mathrm{p}=\mathrm{F} \Delta \mathrm{t}$ (which can be a useful formula!)
We can stick these two formulas together to get

$$
\mathrm{F} \Delta \mathrm{t}=\mathrm{m} \Delta \mathrm{v}
$$

You can see that a change in momentum (impulse) depends on two factors... force and time interval.

- To change an object's momentum, think of the following situations:

1. You could apply a medium force over a medium time interval.

$$
\mathrm{F} \Delta \mathrm{t}=\Delta \mathrm{p}
$$

2. You could apply a big force over a small time interval and get the same impulse as in (1).

$$
\boldsymbol{F}_{\Delta t}=\Delta p
$$

3. Or, you could apply a small force over a long time interval and still get the same impulse.

$$
\Delta t=\Delta p
$$

This explains why you would want to come to a stop by hitting a haystack instead of a brick wall with your car.

- In each case the impulse is the same (your mass stays the same, your $\Delta v$ stays the same).
- When you hit the brick wall...

$$
\mathrm{F}_{\mathrm{su}}=\Delta \mathrm{p}
$$

- Youch! All that force on your body is going to hurt! The impulse happened in a very short time period.
- When you hit the haystack...

$$
{ }_{\mathrm{F}} \Delta \mathrm{t}=\Delta \mathrm{p}
$$

- Not much force at all, since the impulse is spread out over a long time period!

It's the force that "hurts", so you want it to be as small as possible.

- You can use the same argument to explain hitting an airbag instead of a steering wheel, using a bungee cord instead of a rope, or falling onto a wooden floor instead of a cement one.

Example 3: A 75 kg man is involved in a car accident. He was initially traveling at $65 \mathrm{~km} / \mathrm{h}$ when he hit a large truck.
a) If he had no airbag in his car and he came to rest against the steering wheel in 0.05 s , determine how much force was exerted on his body.

First, change $65 \mathrm{~km} / \mathrm{h}$ into $18 \mathrm{~m} / \mathrm{s}$.

$$
\begin{aligned}
& \mathrm{F} \Delta \mathrm{t}=\mathrm{m} \Delta \mathrm{v} \\
& \mathrm{~F}=(\mathrm{m} \Delta \mathrm{v}) / \Delta \mathrm{t} \\
& =(75 \mathrm{~kg})(-18 \mathrm{~m} / \mathrm{s}) \\
& \mathrm{F}=-2.7 \mathrm{e} 4 \mathrm{~N}
\end{aligned}
$$

b) If he did have an airbag that inflated and deflated correctly, bringing him to rest over a time of 0.78 s , determine how much force was exerted on his body.

$$
\begin{aligned}
& \mathrm{F} \Delta \mathrm{t}=\mathrm{m} \Delta \mathrm{v} \\
& \mathrm{~F}=(\mathrm{m} \Delta \mathrm{v}) / \Delta \mathrm{t} \\
& =(75 \mathrm{~kg})(-18 \mathrm{~m} / \mathrm{s}) /(0.78 \mathrm{~s}) \\
& \mathrm{F}=-1.7 \mathrm{e} 3 \mathrm{~N}
\end{aligned}
$$

Which is only about $6 \%$ of the force felt without an airbag... a definite improvement!

## Graphing

At times it can be useful to graph Force vs. Time to determine impulse.

Illustration 1: Graph of Force as a function of Time
What is the area under the graph?
Area $=$ base X height
$=\mathrm{F} \Delta \mathrm{t}$
Area $=$ Impulse

Example 4: I am in a car that is accelerating. I want to calculate the impulse that is acting on the car during this time of 5.78 s . If I know that the force on the car increases from 0 N to 3012 N over this time, calculate the impulse.

Let's start by graphing the information we were given...

Illustration 2: Graph for Example 2 (Force as a function of Time)
If we calculate the area under the graph (in this case a triangle) we will know what the impulse is.

$$
\begin{aligned}
\mathrm{A} & =1 / 2 \mathrm{bh} \\
& =1 / 2(5.78 \mathrm{~s})(3012 \mathrm{~N}) \\
\mathrm{A} & =8.70 \mathrm{e} 3 \mathrm{kgm} / \mathrm{s}
\end{aligned}
$$

Even if it is a curved line, you can still at least estimate the area under the graph...

Illustration 3: Curved Line Graph of Force as a function of Time

- For a curved line like this one, we can figure out the area of a bunch of little columns under the line to approximate the true area.
- If you've taken a calculus course then you'll know that you can make better approximations by assuming an infinite number of columns under the line.
- You are not responsible for calculus calculations in this course... we'd just want you to approximate the values as closely as possible.
